Cardiovascular Check

Summary

Congratulations on taking the Cardiovascular Check which puts you in control of your health data!

i-screen

Collection Date: 26 Mar 2026

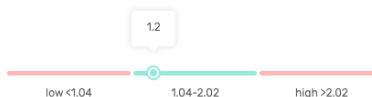

Lipoproteins

Your apo B levels, B/A ratio, and your Lipoprotein (a) levels are elevated which indicate you are at increased risk of cardiovascular disease. Literature data suggests that concentrations greater than 72 nmol/L are associated with a two to five fold increase in cardiovascular risk.

Elevated Lp(a) is a genetic trait – as such there is a 1 in 2 chance that your brothers, sisters and children will also have elevated Lp(a), and the parent you inherited it from will also have elevated Lp(a).

Apolipoprotein A1 1.20 g/L

Apo A is a protein carried in HDL ("good") cholesterol. It helps start the process for HDL to remove bad types of cholesterol from your body. In this way, apolipoprotein A can help to lower your risk for cardiovascular disease.

[results history](#)

Apolipoprotein B 1.51 g/L

Apo B containing lipoproteins are the ones most likely to enter the wall of the arteries. They are capable of trafficking cholesterol into the artery wall, and if present in increased numbers may be the main initiating factor in atherosclerosis.

[results history](#)

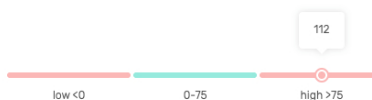

Ratio (APO B / APO A-1) 1.25

The apo B/apo A-I ratio indicates the cholesterol balance between potentially atherogenic (bad) and antiatherogenic (good) particles. The ratio is strongly related to risk of cardiovascular disease. For men the ratio should be 0.9 or under and for women it is 0.8 or under.

[results history](#)

Lipoprotein (a) 112 nmol/L

High levels of Lp(a) increase your risk of atherosclerosis and is an inherited genetic condition. As levels are genetically determined they are usually not lowered by lifestyle changes such as diet and exercise. Your level of

lifestyle changes such as diet and exercise, your level of Lp(a) remains virtually constant throughout your life.

[results history](#)

Inflammation

Your hsCRP levels don't indicate you are at increased risk of cardiovascular disease.

High sensitivity CRP 0.8 mg/L

A high-sensitivity C-reactive protein (hs-CRP) test measures low levels of CRP and may be used to help evaluate an individual for risk of cardiovascular disease.

[results history](#)

Cholesterol

Your lipid profile is outside of normal range as your LDL "bad" cholesterol levels are elevated, which are risk factors for cardiovascular disease.

Your triglycerides are also elevated. The body uses triglycerides and cholesterol differently - triglycerides are a type of fuel, while cholesterol is needed for various metabolic processes such as making particular hormones and building cells. High triglycerides contribute to the development of atherosclerosis (the formation of fatty plaques on blood vessel walls). This may therefore also increase the risk of cardiovascular disease.

As such follow up with your GP is recommended, whilst simple and sustainable lifestyle/dietary changes may assist in bringing these values back down toward normal levels.

Your HDL "protective" cholesterol levels are within range.

Total Cholesterol 6.6 mmol/L

High total cholesterol is a risk factor for cardiovascular disease.

[results history](#)

LDL 4.3 mmol/L

LDL (low density lipoprotein) cholesterol is often called 'bad cholesterol' because it contributes to plaque, a thick, hard deposit that can clog arteries and make them less flexible.

[results history](#)

HDL 0.95 mmol/L

HDL (high density lipoprotein) cholesterol is often called 'good cholesterol' and is protective against atherosclerosis.

[results history](#)

Triglycerides 3.0 mmol/L

The main storage form of fatty acids in the body. Elevated triglyceride levels may contribute to hardening of the

arteries, and increase the risk of heart disease or stroke.

low <0

0-2

high >2

[results history](#)

Cholesterol Ratio 6.9 mmol/l

A calculation of your HDL cholesterol over your total cholesterol which is used to calculate your likelihood of developing heart disease.
