Collection Date: 26 Mar 2026

Insulin

Your fasting insulin levels are elevated. Fasting serum insulin levels can suggest moderate or severe insulin resistance. Small amounts of insulin are normally produced after eating which the body uses to turn glucose into energy. Insulin resistance is where the muscles and the liver resist the action of insulin, so the body has to produce higher amounts to keep the blood glucose levels within a normal range. Insulin resistance can significantly affect lipids by increasing triglycerides and LDL 'bad' cholesterol, and decreasing HDL 'good' cholesterol. When the body's insulin production can't keep up, blood sugar increases and over time can progress to diabetes.

Insulin 126 pmol/L

A hormone produced by the pancreas that helps to control blood glucose levels and plays a role in controlling the levels of carbohydrates and fats stored in the body.
